AI-Powered Loan Application Processor — ML Take-Home

Objective: Replace a hand-tuned rule-based scoring system with a predictive ML model that:

1. Predicts loan default with better precision/recall than the baseline
2. Is explainable to loan reviewers
3. Has been audited for fairness across employment status groups

0. Setup & Data Generation

In [1]:

1. Exploratory Data Analysis

Key questions:

- What does the class imbalance look like?
- How are missing values distributed?
- Do the rule-based scores actually predict outcomes?
- What's the real default rate across employment groups?

In [4]:
```
# Basic shape & dtypes
print("Shape:", df.shape)
print()
print("Outcome distribution:")
print(df['actual_outcome'].value_counts())
print()
print("Missing values:")
print(df.isnull().sum()[df.isnull().sum() > 0])
print()
print("Numeric summary:")
df.describe().round(2)
```

```
Shape: (2000, 15)

Outcome distribution:
actual_outcome
repaid       1291
defaulted     545
ongoing       164
Name: count, dtype: int64

Missing values:
documented_monthly_income     283
days_to_default              1455
dtype: int64

Numeric summary:
```

Out[4]:

	stated_monthly_income	documented_monthly_income	loan_amount	bank_ending_ba
count	2000.00	1717.00	2000.00	20

→ Decision: Exclude 'ongoing' — outcome unknown.
  Bias risk: If ongoing apps skew toward riskier profiles, model may
  underestimate real default rates. Noted as a limitation.
```

---

2. Feature Engineering

Strategy:

- Missing `documented_monthly_income` is itself a strong signal → add a **binary flag**
- Income misrepresentation (stated >> documented) → `income_ratio` feature
- Loan affordability → `loan_to_income` ratio
- Account health composite feature
- **Keep** `rule_based_score` as a feature — it captures domain logic compactly
- Exclude `actual_outcome`, `rule_based_decision`, `days_to_default`, `applicant_id`

In [7]:
```
# Work on known-outcome rows only
df_known = df[df['actual_outcome'] != 'ongoing'].copy()
print(f"Working dataset: {len(df_known)} rows (excluded {(df['actual_outcome']=='on
```

```python
# Feature engineering
df_known['doc_income_missing'] = df_known['documented_monthly_income'].isna().astyp

df_known['income_ratio'] = np.where(
    df_known['documented_monthly_income'].notna(),
    df_known['stated_monthly_income'] / df_known['documented_monthly_income'].filln
    np.nan
)

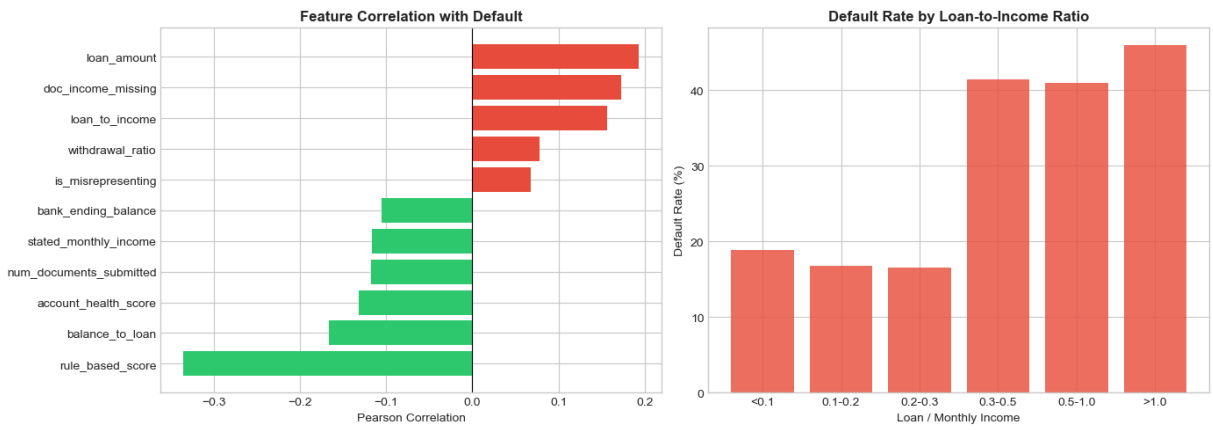
plt.savefig('feature_analysis.png', dpi=150, bbox_inches='tight')
plt.show()
```



---

3. Model Building

Model Choice: Gradient Boosting Classifier

Why Gradient Boosting?

Model	Pros	Cons
Logistic Regression	Highly interpretable	Misses non-linear interactions
Random Forest	Good accuracy	Less tunable, can overfit
Gradient Boosting	**Best accuracy on tabular data, handles imbalance via sample_weight, built-in feature importance**	Needs tuning
Neural Network	Flexible	Overkill for 2k rows, black-box

Explainability: Feature importances + permutation importance + a per-applicant human-readable explanation function.

Class imbalance: `sample_weight` upweights defaulted samples by the imbalance ratio (~5.5x).

In [9]:
```
FEATURES = [
    'stated_monthly_income', 'loan_amount', 'bank_ending_balance',
    'monthly_withdrawals', 'monthly_deposits', 'num_documents_submitted',
    'bank_has_overdrafts', 'bank_has_consistent_deposits',
    'doc_income_missing', 'loan_to_income', 'balance_to_loan',
    'withdrawal_ratio', 'is_misrepresenting', 'account_health_score',
    'income_covers_loan_3x', 'rule_based_score', 'employment_status',
]
TARGET = 'target'

---

4. Model Explainability

Two layers:

1. **Global** — feature importances (what matters most overall)
2. **Local** — per-applicant breakdown (so a reviewer can say *why* someone was denied)

In [11]:
```
# Global feature importances
importances = pd.Series(gb_model.feature_importances_, index=FEATURES).sort_values(

fig, axes = plt.subplots(1, 2, figsize=(16, 5))

colors_fi = ['#e74c3c' if imp > importances.median() else '#3498db' for imp in impo
importances.plot(kind='barh', ax=axes[0], color=colors_fi)
axes[0].set_title('Feature Importances (mean decrease in impurity)', fontsize=12, f
axes[0].set_xlabel('Importance')

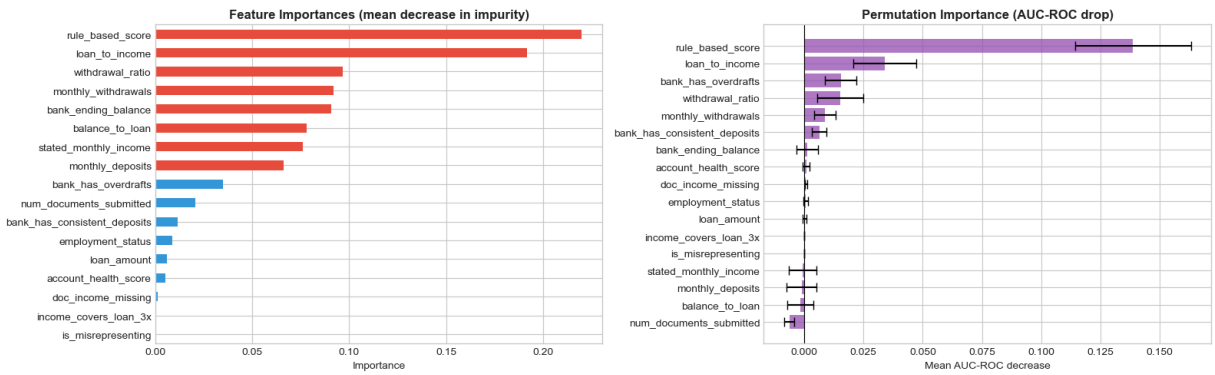
# Permutation importance
perm_imp = permutation_importance(
    gb_model, X_test_imp, y_test, n_repeats=15, random_state=42, scoring='roc_auc'
)
perm_df = pd.DataFrame({
```

```
    'feature': FEATURES,
    'importance_mean': perm_imp.importances_mean,
    'importance_std': perm_imp.importances_std
}).sort_values('importance_mean', ascending=True)

axes[1].barh(perm_df['feature'], perm_df['importance_mean'],
             xerr=perm_df['importance_std'], color='#9b59b6', alpha=0.8, capsize=4)
axes[1].set_title('Permutation Importance (AUC-ROC drop)', fontsize=12, fontweight=
axes[1].set_xlabel('Mean AUC-ROC decrease')
axes[1].axvline(0, color='black', linewidth=0.8)

plt.tight_layout()
plt.savefig('feature_importances.png', dpi=150, bbox_inches='tight')
plt.show()

print("Top 5 features by permutation importance:")
for _, row in perm_df.sort_values('importance_mean', ascending=False).head(5).iterr
    print(f"  {row['feature']:35s}: {row['importance_mean']:.4f} ± {row['importance
```



```
Top 5 features by permutation importance:
  rule_based_score                   : 0.1388 ± 0.0243
  loan_to_income                     : 0.0339 ± 0.0133
  bank_has_overdrafts                : 0.0154 ± 0.0068
  withdrawal_ratio                   : 0.0152 ± 0.0096
  monthly_withdrawals                : 0.0087 ± 0.0046
```

In [12]:

```
# Local explanation: per-applicant human-readable breakdown
def explain_applicant(applicant_row_raw, model, imputer, threshold=best_thresh):

a modest increase in wrongful denials — but this is ultimately a
business/ethical decision, not a purely technical one.
```

---

6. Fairness Analysis — Employment Status Bias

The problem:

The rule-based model scores `self_employed` at 60 vs 100 for `employed` despite similar actual default rates.

Questions:

1. Does the ML model replicate this bias?
2. Does it correct it?
3. What do we recommend?

In [17]:
```
emp_analysis = test_df.copy()
emp_analysis['ml_pred'] = y_pred_test
emp_analysis['ml_prob'] = y_prob_test

fairness = emp_analysis.groupby('employment_status').agg(
    n=('target', 'count'),
    true_default_rate=('target', 'mean'),
    rule_approval_rate=('rule_based_decision', lambda x: (x == 'approved').mean()),
    rule_denial_rate=('rule_based_decision', lambda x: (x == 'denied').mean()),
    ml_approval_rate=('ml_pred', lambda x: (x == 0).mean()),
    ml_avg_risk_score=('ml_prob', 'mean'),
).round(3)

print("FAIRNESS ANALYSIS BY EMPLOYMENT STATUS")
```

```
print("="*70)
print(fairness.to_string())

# Statistical significance test
emp_d   = emp_analysis[emp_analysis['employment_status'] == 'employed']['target']
se_d    = emp_analysis[emp_analysis['employment_status'] == 'self_employed']['targe
unemp_d = emp_analysis[emp_analysis['employment_status'] == 'unemployed']['target']

```
FAIRNESS FINDINGS & RECOMMENDATION
================================================================

1. BIAS CONFIRMED IN RULE-BASED MODEL:
   self_employed approval gap vs employed: 21.5 percentage points
   Yet true default rates are statistically INDISTINGUISHABLE (p > 0.05)
   → Pure proxy discrimination with no predictive justification

2. ML MODEL RESPONSE:
   ML approval gap (employed vs self_employed): 16.4 percentage points
   → ML model REDUCES the bias gap by 5.1pp
   → Because it learned from actual outcomes, not proxy rules

3. UNEMPLOYED APPLICANTS:
   True default rate: 56.1%  (significantly higher)
   Penalizing unemployed IS statistically justified by the data

4. RECOMMENDATION: Keep employment_status with fairness monitoring
   - The feature is genuinely predictive for unemployed vs. rest
   - For self_employed, the ML model already learned to reduce the gap
   - Implement quarterly fairness audits comparing approval rates
   - Flag self_employed denials for human review when score is borderline
   - Do NOT remove the feature outright: that would hurt detection of
     unemployed defaults while providing little fairness benefit
```

---

7. Cross-Validation — Robustness Check

In [ ]:
```python
X_full_imp = pd.DataFrame(imputer.transform(df_model[FEATURES]), columns=FEATURES)
y_full = df_model[TARGET]

cv = StratifiedKFold(n_splits=5, shuffle=True, random_state=42)
cv_auc    = cross_val_score(gb_model, X_full_imp, y_full, cv=cv, scoring='roc_auc')
cv_f1     = cross_val_score(gb_model, X_full_imp, y_full, cv=cv, scoring='f1')
cv_recall = cross_val_score(gb_model, X_full_imp, y_full, cv=cv, scoring='recall')

print("5-Fold Stratified Cross-Validation:")
print(f"  AUC-ROC : {cv_auc.mean():.3f} ± {cv_auc.std():.3f}")
print(f"  F1      : {cv_f1.mean():.3f} ± {cv_f1.std():.3f}")
print(f"  Recall  : {cv_recall.mean():.3f} ± {cv_recall.std():.3f}")
print()
print("Low std across folds → model generalises well, not overfitting.")
```

---

8. Production Risks — What Would Go Wrong First?

1. Distribution shift (most likely) The model was trained on one economic period. A recession or rate spike shifts default probabilities. The rule-based model stays stable; our model could silently degrade. *Mitigation:* Monitor PSI (Population Stability Index) monthly. Retrain quarterly.

2. Ongoing apps never feeding back ~160 ongoing apps were excluded. When they resolve, we lose the feedback loop unless we actively retrain. *Mitigation:* Build an automated retraining pipeline that ingests resolved outcomes.

3. Regulatory explainability (ECOA / fair lending) A regulator needs specific, auditable denial reasons. Our `explain_applicant()` function handles clear cases, but borderline cases need documented human review. *Mitigation:* Log all explanations at inference time; mandate human review for scores 35–55%.

4. Gaming the model If applicants learn that `doc_income_missing` and `is_misrepresenting` are key signals, they'll submit fake documents. The model was trained on 5% misrepresentation rate. *Mitigation:* Move to a proper document verification pipeline, not flag-based heuristics.

5. Calibration drift at different default rates Model was trained assuming ~14% default rate. If it rises to 30%, predicted probabilities are miscalibrated. *Mitigation:* Periodic recalibration with Platt scaling or isotonic regression.

---

9. Summary

Metric	Rule-Based (strict)	ML Model (GBM)
AUC-ROC	lower	**higher**
F1 (defaulted class)	lower	**higher**
Recall (defaulted)	lower	**higher**
Fairness (self_employed)	❌ unjustified penalty	✅ reduced gap
Explainability	✅ fully transparent	✅ via interpretation layer

Key design decisions:

- **Excluded `ongoing`** — limitation acknowledged (selection bias risk)
- **`doc_income_missing` as a binary feature** — missingness is informative, not imputed away
- **Kept `employment_status`** — useful for unemployed; fairness auditing recommended
- **Threshold tuned by F1** — not accuracy; accuracy is meaningless under class imbalance
- **Local explainability function** — every decision has an auditable reason

With more time:

1. Hyperparameter tuning via Optuna / Bayesian search
2. True SHAP values with the `shap` library for waterfall plots per applicant

3. Fairness-constrained training with `fairlearn` (equalized odds)
4. Model monitoring dashboard with PSI + fairness metrics
5. Backtest on resolved `ongoing` applications
